Often a more efficient solution for image processing tasks is to use an FPGA rather than a microprocessor since it allows massive parallelisation and pipe-lining, and implements algorithms directly in logic hardware rather than sequential software instructions so that very sophisticated image processing can be achieved at relatively low clock rates, an FPGA running at just 50 MHz can easily outperform a desktop class processor when performing specialised tasks.

Although the most modern sensors feature some processing at the point of collection, most images don't come out of the front end of the camera fit to be seen, much less understood. Images may be distorted and vertigo-inducing as a result of the motion of the sensor, as the gimbal swivels, and as the platform moves due to engine vibration, flight maneuvers, and turbulence.
