But everything has posited that we know the graph somehow. This chapter finally deals with where the graph comes from. There are fundamentally three ways to get the DAG: • Prior knowledge • Guessing-and-testing • Discovery algorithms

Discovering Causal Structure from Observations

The result is a widely-applicable method that infers causal structure directly from observations of a system's behaviors whether they are over discrete or continuous events or time. A structural representation -- a finite- or infinite-state kernel ϵ -machine -- is extracted by a reduced-dimension transform that gives an efficient representation of causal states and their topology.

Infer one link of a causal structure, from observations

Causal discovery aims to find causal relations by analyzing observational data. The data are produced by not only the underlying causal process, but also the sampling process. In practice, to achieve reliable causal discovery, one needs to address specific challenges posed in the causal process or the sampling process.

The paper presented a novel approach for discovering causal dependencies between events recorded in large volumes of H&S data. The approach is based on the notion of proximity of H&S observations and incidents. The proposed approach was evaluated through a case study conducted in an Australian energy company.

Inductive reasoning is a method of reasoning in which the premises are viewed as supplying some evidence, but not full assurance, of the truth of the conclusion. It is also described as a method where one's experiences and observations, including what are learned from others, are synthesized to come up with a general truth. Many dictionaries define inductive reasoning as the derivation of ...

Discovering Causal Structure From Observations

Many real-world studies and experiments are characterized by an underlying spatial structure that induces dependencies between observations. Most existing causal discovery methods, however, rely on the IID assumption, meaning that they are ill-equipped to handle, let alone exploit this additional information.

Causal Discovery with General Non-Linear Relationships ...

Causal inference is the general problem of deducing cause-effect relationships among variables [41, 31, 32, 40, 6, 42]. “Causal discovery” approaches allow causal inference from pre-recorded observations under constraints [43, 12, 22, 10, 23, 24, 20, 9, 27, 45]. Observational causal inference is known to be impossible in general [31, 33].

Causal Confusion in Imitation Learning

Discovering causal structure of a dynamical system from observed time series is a traditional and important problem. In many practical applications, observed data are obtained by applying subsampling or temporally aggregation to the original causal processes, making it difficult to discover the underlying causal relations.

observations we wish to predict from X . A common example would be future sequences (possibly truncated, as just noted) that occur at time $t > 0$.

We also assume Y is defined on a measurable space $Y, \mathcal{B}_Y, \nu_Y$. A prediction then is the distribution of outcomes Y given observed system configuration $X = x$ at time t , denoted $\Pr(Y|X = x)$. This same definition extends to non-tem-

causal inference programs are hidden by layers of formal technique. Therefore, it is important to make the ideas explicit and probe them carefully. SGS illustrate the problem; these authors contend they have algorithms for discovering causal relations based only on empirical data, with little or no need for subject-matter knowledge.

Are There Algorithms That Discover Causal Structure?

Observational causal inference is known to be impossible in general [36, 37]. We operate in the interventional regime [53, 10, 47, 46] where a user may “experiment” to discover causal structures by assigning values to some subset of the variables of interest and observing the effects on the rest of the system.
