Genetic Engineering Of Mammalian Cells

Genetic engineering in mammalian cells calls for additional steps. Ways must be found to introduce the desired gene, purified and amplified by cloning in bacteria, into a mammalian cell. Then ways must be found to express the gene: to get the DNA of the gene transcribed into messenger RNA and to get the messenger RNA translated into protein.

Genetic Engineering in Mammalian Cells

Various genetic tools that allow precise DNA modifications have been developed to achieve loss- and gain-of-function strategies in mammalian cells. DNA recombination by site specific

recombinases (SSR) like Cre or FLP developed into an extremely valuable approach to manipulate the genome of a wide variety of cells.

Genetic engineering can be accomplished using multiple techniques.

There are a number of steps that are followed before a genetically modified organism (GMO) is created. Genetic engineers must first choose what gene they wish to insert, modify, or delete. The gene must then be isolated and incorporated, along with other genetic elements, into a suitable vector.

Abstract. Stem cell therapy is a promising strategy for overcoming the limitations of current treatment methods. The modification of stem cell properties may be necessary to fully exploit their potential. Genetic engineering, with an abundance of methodology to induce gene expression in a precise and well-controllable manner, is particularly attractive for this

purpose.

Genetic engineering of stem cells for enhanced therapy
