Pipelining is an important technique used in several applications such as digital signal processing systems, microprocessors, etc. It originates from the idea of a water pipe with continuous water sent in without waiting for the water in the pipe to come out. Accordingly, it results in speed enhancement for the critical path in most DSP systems. For example, it can

either increase the clock speed or reduce the power consumption at the same speed in a DSP system.

For a non pipelined implementation it takes 800ps for each instruction and for a pipelined implementation it takes only 200ps. Observe that the MIPS ISA is designed in such a way that it is suitable for pipelining. Figure 10.3 shows the MIPS pipeline implementation. – All instructions are 32-bits. Implementation status. Pipelining was introduced in HTTP/1.1 and was not present in HTTP/1.0. Implementation in web servers. Implementing pipelining in web servers is a relatively simple matter of making sure that network buffers are not discarded between requests. For that reason, most modern web servers handle pipelining without any problem.

Pipelined datapath and control. A pipeline processor can be represented in two dimensions, as shown in Figure 5.1. Here, the pipeline segments (Seg #1 through Seg #3) are arranged vertically, so the data can flow from the input at the top left downward to the output of the pipeline (after Segment 3). The progress of an instruction is charted in blue typeface, and the next instruction is shown in red typeface.
