Entropy Problems And Solutions

There is an entropy change associated with the formation of a solution, an increase in entropy (randomness) that thermodynamically favors the solution over the two original states. If the other energetics of dissolution are favorable, this increase in entropy means that the conditions for solubility will always be met.

Solutions and Entropy Changes | Introduction to Chemistry

The entropy of a reaction refers to the positional probabilities for each reactant. For instance, an atom in its gas phase

has more options for positions than the same atom in a solid phase. This is why gases have more entropy than solids. In reactions, the positional probabilities must be compared for all the reactants to the products produced. Therefore, if the reaction involves only gases, the entropy is related to the total number of moles on either side of the reaction.

Learn How to Solve an Entropy Change Problem

Find the change in entropy if 500 g of water at 80°C is added to 300 g of water at 20°C. The total amount of water is 800g, so the final temperature of the system is given by $5 \times 8 \times 353\text{K} + 3 \times 8 \times 293\text{K} = 330.5\text{K}$. For $m_1 = 500\text{ g}$ and $m_2 = 300\text{ g}$, the entropy change is given by $\Delta S = \int \frac{dQ}{T} = 2330.5 \text{ J/K}$.

The value of the entropy corresponds exactly to random mixing for ideal solutions and for regular solutions, and approximately so for many real solutions. For binary mixtures the entropy of random mixing can be considered as a function of the mole fraction of one component.
