Title: reaction of aldehydes and ketones Introduction: An aldehyde is an organic compound containing a formyl group. This functional group, with the structure R-CHO, consists of a carbonyl center bonded to hydrogen and an R group. The group without R is called the aldehyde group or formyl group. Aldehydes differ from ketones in that the carbonyl is placed at the end of a carbon skeleton rather ...

How will you distinguish between aldehyde and ketone?

Among the most useful and characteristic reactions of aldehydes and ketones is their reactivity toward strongly nucleophilic (and basic) metallo-hydride, alkyl and aryl reagents. If the carbonyl functional group is converted to an acetal these powerful reagents have no effect; thus, acetals are excellent protective groups, when these irreversible addition reactions must be prevented.

The most common reaction of aldehydes and ketones is nucleophilic addition. This is usually the addition of a nucleophileand a protonacross the C=O double bond. As the nucleophile attacks the carbonyl group, the carbon atom changes from sp2to sp3. The electrons of the π bond are pushed out onto the oxygen, generating an alkoxide anion.

Ozonolysis is a reaction method in which addition of ozone molecules or O 3 to an alkene compound leads to the formation of ozonide. Reduction of the ozonide compound with the help of zinc dust and water produces the smaller molecules, which in this case will be the respective aldehydes and ketones.
