Abstract. The process of determining the frequency contents of a continuous-time signal in the discrete-time domain is known as spectral analysis. Most of the phenomena that occur in nature can be characterized statistically by random processes. Hence, the main objective of spectral analysis is the determination of the power spectrum density (PSD) of a random process.

The cepstrum is a Fourier analysis of the logarithmic amplitude spectrum of the signal. If the log amplitude spectrum contains many regularly spaced harmonics, then the Fourier analysis of the spectrum will show a peak corresponding to the spacing between the harmonics: i.e. the fundamental frequency. Effectively we are treating the signal spectrum as another signal, then

The frequency spectrum of a typical speech signal is shown in Fig. 9.7a. It shows that even though speech can have frequencies as high as 10 kHz, much of the spectrum is concentrated within 100 to 700 Hz, with it sounding quite natural when the bandwidth is restricted to 3 kHz. Show the necessary design steps to transmit this as a digital voice signal over telephone lines.
