Mark and recapture is a method commonly used in ecology to estimate an animal population's size where it is impractical to count every individual. A portion of the population is captured, marked, and released. Later, another portion will be captured and the number of marked individuals within the sample is counted. Since the number of marked individuals within the second sample should be

proportional to the number of marked individuals in the whole population, an estimate of the total population

Mark and recapture - Wikipedia

A frequently used method for sampling such populations is the mark-recapture technique. In its simplest form, this method consists of capturing some individuals, marking them in some way, releasing them back into the population, and, after an appropriate time interval, resampling the population.

Capture-Mark-Recapture (CMR) can be viewed as an animal survey method in

which the count statistic is the total number of animals caught, and the associated detection probability is the probability of capture.

Capture-Mark-Recapture Science - USGS

Capture-recapture or mark-recapture is a method, for estimating population size and other parameters, that is based on ratios of marked to unmarked individuals. Perhaps the most famous early application of capture-recapture was

estimation, by Pierre Simon Laplace, of the population size of France in 1802 (Cochran, 1978; Stigler, 1986).
